GROWTH TABLES FOR SELECTIVELY-CUT PONDEROSA PINE

IN WESTERN MONTANA

by

Arthur L. Roe [1]

INTRODUCTION

A study of cut-over ponderosa pine stands in western Montana was made in 1947 in answer to forest managers' requests for ways to predict growth of selectively-cut ponderosa pine timber. Growth responses to different intensities of cutting were analyzed on 60 half-acre temporary sample plots. Age of cutting varied from 5 to 50 years.

From the data obtained, a set of yield tables has been developed for predicting growth of residual trees after logging. The eight growth tables, and methods for their use, are the subject of this report. They are presented on pages 6 to 13. Two kinds of estimates can be made from these tables:

1. A general estimate of growth of residual stands on areas containing typical, or average, conditions, to be used principally for broad planning purposes.

2. A more precise prediction of the growth of residual stands which includes adjustments for stand competition, site index, and maturity.

HOW TO USE THE TABLES TO PREDICT BOARD-FOOT GROWTH IN CUT-OVER STANDS

GENERAL ESTIMATES

Growth may be estimated as an average figure which will be applicable to average or typical residual stands. Tables 1, 2, and 3 show average volume of residual trees by reserve stand classes up to 50 years after cutting by five-year intervals and site classes. The volumes given are net because mortality has been deducted. Table 1 represents growth estimates for typical or average site class conditions on cut-over areas

in western Montana. Tables 2 and 3 show values for site classes IV and V, respectively. To convert the values found in these tables to other site classes, use a 12-percent adjustment factor between site classes. For example, the values found in the site class IV tables when multiplied by 112 percent will be converted to corresponding values for site class III.

The board-foot volume of the reserve stand (trees 10 inches d.b.h. and larger at logging) and site class are the only stand statistics needed in order to use tables 1, 2, and 3. Site classification tables are presented in appendix tables 1 and 2. For example, assume that selective cutting in a ponderosa pine stand averaging site class IV left a reserve stand of 4500 board feet per acre and that the predicted volume of this stand in 30 years is required. The average volume of the residual stand 30 years later would be found as follows: (1) enter table 2 at the 4500 board-foot reserve stand class (interpolate between 4,000 and 5,000 board feet); (2) read the values in the 30-year column. The volume will be 6920 board feet 30 years after logging, representing a net growth of 2420 board feet (6920 bd. ft. - 4500 bd. ft.) in 30 years, or 80.7 board feet periodic annual growth. Ingrowth must be computed independently because it has not been included in these tables.

ADJUSTING GROWTH ESTIMATES FOR ADDITIONAL VARIABLES

To refine the growth prediction, greater knowledge is required concerning the reserve stand. The following information will be needed:

1. A stand table of the residual trees in the 1-inch d.b.h. class and larger.

2. Basal area of the reserve stand 9.6 inches d.b.h. and larger.

3. Site index (height in feet of the average dominant and codominant trees at 100 years). See appendix tables 1 and 2.

4. Age of residual trees - obtained by taking a weighted average of Keen age classes of sample residual trees.

After basal area has been derived from the stand table, summarize the survey data from the cut-over stand and compute growth as shown in the following example:

Reserve stand data:

1. Volume - 5000 board feet

2. Basal area - 50 square feet

3. Site index - 70 feet at 100 years (Site Class V)

4. Keen age - 2.6

5. Cutting cycle - 35 years

Growth compilation:

1. Derive gross growth by reading from table 4 for the correct basal
   area (50) and cutting cycle (35). In this instance, gross growth
   is 4850 board feet. Interpolate when values are intermediate to
   those shown in the table.

2. Obtain a correction factor (94 percent) for age (2.6) and site
   index (70) from table 5. This reduces growth to 4559 board feet
   (4850 X 0.94).

3. Take out mortality with the 15 percent average found in the
   study. 4559 - (.15 X 4559) or 4559 X 0.85 = 3875 board feet.
   This is net growth of the residual trees. In case the user of the
   table has at hand a more exact mortality correction factor for
   his particular stand, it should be used instead of the 15 percent
   average.

4. Sum the reserve stand volume and net growth to obtain net volume
   of the residual trees at the end of the cutting cycle or 5000 +
   3875 = 8875 board feet per acre. Periodic annual growth is
   3875/35 = 111 board feet.

5. Set up a stand table for determination of ingrowth, using field
   survey data as shown below:

| D.B.H. class in inches | Trees per acre | |
	Ponderosa pine (Number)	Douglas-fir (Number)
3	--	--
4	--	--
5	.19	2.75
6	--	2.17
7	.37	1.90
8	--	1.28
9	.92	.83
Total	1.48	8.93

6. Compute ingrowth from tables 6, 7, and 8 and the stand table prepared in step 5. Tables 6, 7, and 8 show the board-foot volume of pole size trees by five-year intervals after logging. In our problem, both ponderosa pine in site class V and Douglas-fir are present. Therefore, values for the solution are taken from table 7 for ponderosa pine and from table 8 for Douglas-fir. Values, read from the proper diameter class and five-year interval in the table, should be multiplied by the number of trees in the corresponding diameter class in the stand table. Thus, in the example there is 0.37 ponderosa pine tree per acre in the 7-inch d.b.h. class. A volume of 41 board feet is shown in table 7 for the volume of a 7-inch tree 35 years after logging. This volume multiplied by the number of trees per acre in the stand table will then give the volume per acre (41 X .37 = 15.17 bd. ft.). A tabulation like the following will be the result when volumes for the other diameter classes have been computed.

D.B.H. Class (Inches)	Ingrowth volume summary per acre	
	Ponderosa pine	Douglas-fir
	Bd. ft.	Bd. ft.
3	--	--
4	--	--
5	3/ 0.00	4/ 85.25
6	--	84.63
7	4/ 15.17	85.50
8	--	67.84
9	71.76	49.80
Total	86.93	373.02

3/ By referring to table 7, it will be seen that a five-inch ponderosa pine does not attain merchantable size in 35 years.
4/ Number of trees per acre times volume per tree.

The products derived are net values because average mortality has been deducted from pole volumes in the tables.

7. Obtain total volume of the stand 35 years after logging by
   summing the volume of residual trees and ingrowth. Computa-
   tions follow:

    Volume of residual trees at end of
      35-year cutting cycle . . . . 8875 bd. ft.

    Ingrowth
      Ponderosa pine . . . .   87 "   "
      Douglas-fir . . . . <u>373</u> "   "

    Total predicted volume of stand 10" d.b.h.
      and larger at end of 35-year cutting
      cycle . . . . 9335 "   "

    Periodic annual growth

$$\frac{3875 \text{ bd. ft. } + \; 87 \text{ bd. ft. } + \; 373 \text{ bd. ft.}}{35} \; = \; 124 \text{ " "}$$

LIMITATIONS ON USE OF TABLES

Two limitations of which the user should be aware apply to prediction
of growth from these tables. One limitation pertains to species composi-
tion of stands. The stands studied contained, on the average, 77 percent
ponderosa pine and 23 percent Douglas-fir by basal area. Hence, these
tables should be used only for predicting growth of stands which are pre-
dominantly ponderosa pine. The other limitation applies to predicting
growth in stands which have been cut two or more times. Growth estimates
from the tables should not be applied directly unless growth in a cut-over
stand has dropped back to about the pre-logging rate. If a stand is still
benefiting from the stimulating effect of thinning caused by a previous
logging, its initial growth rate at the time of the second cutting will
be higher than the initial rate given in the growth tables. Therefore,
the tables will generally underestimate growth after a second cutting.
By adjusting for the higher initial growth at the time of second or later
cuttings, the tables would be improved but the degree of improvement and
the reliability of estimates would be unknown. The growth values in tables
1, 2, 3, and 4 should not be extended in order to permit prediction of
growth in stands more heavily stocked than shown in the tables. It is
probable that growth in more heavily stocked stands is influenced by
stand density.

1/ Volumes are given for trees 9.6 inches d.b.h. and larger.
2/ Volumes in this table have been reduced by 5 percent to account for average mortality.

APPENDIX TABLES

Appendix table 1.—Height of dominant and codominant trees of average breast-height diameter 1/

Age (years)	Height, by site index—												
	40	50	60	70	80	90	100	110	120	130	140	150	160
	Feet	Feet	Feet	Feet	Feet	Feet	Feet	Feet	Feet	Feet	Feet	Feet	Feet
20	6	9	12	16	20	25	30	35	40	45	50	55	60
30	11	15	20	26	32	38	44	51	57	64	70	77	84
40	16	22	28	35	42	49	55	63	70	77	85	93	100
50	21	28	35	43	51	58	65	73	80	89	97	105	113
60	26	34	42	50	58	66	73	81	90	99	107	115	124
70	30	39	47	56	64	73	80	89	98	108	116	125	134
80	34	43	52	61	70	79	88	97	106	116	124	133	143
90	37	47	57	66	75	85	94	104	113	123	132	142	152

1/ Meyer, W. H., "Yield of even-aged stands of ponderosa pine."
U. S. Dept. of Agr. Tech. Bul. 630, 60 pp., illus. 1938.

Appendix table 2.--Site-quality classification for ponderosa pine,

with corresponding heights at maturity

in terms of logs. 1/

Site quality class	Site index at 100 years		Logs in dominant trees at maturity 2/
	Central value	Range	
	Feet	Feet	Number
I...................	120	+113	10 or more
II..................	106	99--112	8 to 9
III.................	92	85--98	7
IV..................	78	71--84	5 to 6
V...................	64	57--70	3 to 4
VI..................	50	43--56	2.
VII.................	36	43-	2-

1/ Meyer, W. H., "Yield of even-aged stands of ponderosa pine."
U. S. Dept. of Agr. Tech. Bul. 630, 60 pp., illus. 1938.
2/ Estimated in terms of 16-foot logs to 8-inch top. Maturity is assumed
to begin at the age of 250 years.

17   Disintegration of girdled western hemlock and grand fir,
      by Austin E. Helmers. December 1948.

18   *Suggested Montana Douglas-fir Christmas tree standards,
      by S. Blair Hutchison and Ben M. Huey. January 1949.

19   *The possibilities of modifying lightning storms in the
      northern Rockies, by Vincent J. Schaefer. January 1949.

20   Forest resources of southern Montana, by W. C. Hodge,
      C. W. Brown, and T. L. Finch. May 1949.

21   Forest resources of Northeast Washington, by Paul D. Kemp
      and H. J. Pissot. May 1949.

22   Bibliography of ponderosa pine, by A. L. Roe and K. N. Boe.
      March 1950.

23   Forest resources of south central Montana, by T. L. Finch,
      W. C. Hodge, and M. E. Metcalf. April 1950.

24   The cubic foot as a national log-scaling standard, by
      E. F. Rapraeger. June 1950.

25   Montana forest resource and industry statistics, by
      Paul D. Kemp and M. B. Dickerman. October 1950.

26   St. Johnswort on western ranges, by Grant A. Harris.
      February 1951.

27   Sampling in tree measurement sales in northern region
      national forests, by Donald W. Lynch and Roy A. Chapman.
      March 1951.

28   Forest fires in the northern Rocky Mountains, by J. S.
      Barrows. April 1951.

29   Fire behavior in the northern Rocky Mountain forests,
      by J. S. Barrows. May 1951.

30   Growth tables for cut-over larch--Douglas-fir stands in the
      Upper Columbia Basin, by Arthur L. Roe. June 1951.

31   Publications of the Northern Rocky Mountain Forest and Range
      Experiment Station, 1912 through 1950. NRM Station.
      July 1951.

*Out of print. Loan copies may be obtained upon request.
